

# **Computer Security: Principles and Practice**

## **Chapter 4 – Access Control**

# Access Control

- “The prevention of unauthorized use of a resource, including the prevention of use of a resource in an unauthorized manner”
- central element of computer security
- assume have users and groups
  - authenticate to system
  - assigned access rights to certain resources on system

# Access Control Principles

# Access Control Policies

- Discretionary Access Control (DAC)
  - Based on identity / group of requestors
  - An entity can extend to other entities the permissions
- Mandatory Access Control (MAC)
  - Security labels on resources
  - Policy controlled by the administrator
- Role-Based Access Control (RBAC)
  - Based on the roles of the users

# Access Control Elements

- subject - entity that can access objects
  - a process representing user/application
  - often have 3 classes: owner, group, world
- object - access controlled resource
  - e.g. files, directories, records, programs etc
  - number/type depend on environment
- access right - way in which subject accesses an object
  - e.g. read, write, execute, delete, create, search

# Discretionary Access Control

- often provided using a 2D access matrix
  - lists subjects in one dimension (rows)
  - lists objects in the other dimension (columns)
  - each entry specifies access rights of the specified subject to that object
- Do you see any **problem** with this representation?

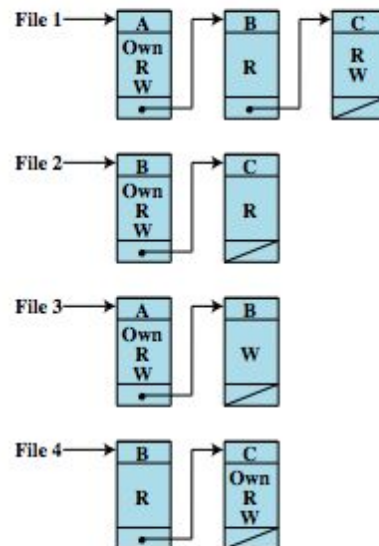

# Discretionary Access Control

- often provided using a 2D access matrix
  - lists subjects in one dimension (rows)
  - lists objects in the other dimension (columns)
  - each entry specifies access rights of the specified subject to that object
- Do you see any **problem** with this representation?
- access matrix is often sparse
- can **decompose** by either row or column

# Access Control Structures

		OBJECTS			
		File 1	File 2	File 3	File 4
SUBJECTS	User A	Own Read Write		Own Read Write	
	User B	Read Write	Own Read Write	Write	Read
	User C	Read Write	Read		Own Read Write

(a) Access matrix

(b) Access control lists for files of part (a)

(c) Capability lists for files of part (a)

# Access Control Structures

- Access Control List: list of users for each object
  - Pros
    - We can set default permissions
    - Easy to define groups permissions
  - Cons
    - Not optimize for determining access rights of users
- Capability tickets
  - Pros
    - Easy to determine set of rights of users
  - Cons
    - Tickets must be hold by OS

# Access Control Model

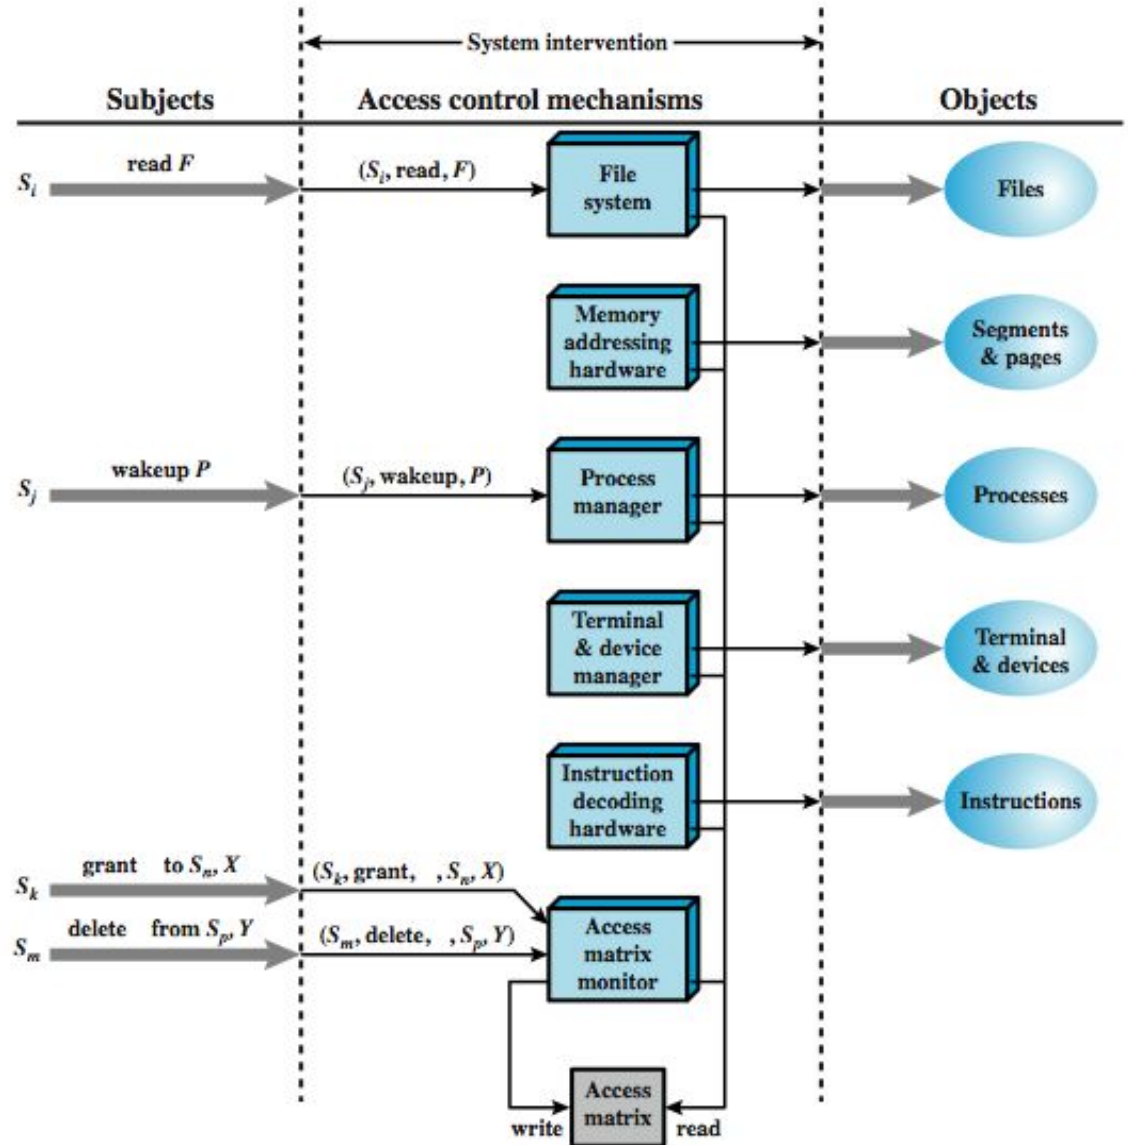

- We want to generalize the DAC model
- Three main requirements
  - Good representation
  - Enforcing the access rights
  - Capability of users to alter specific rights
- Extension of the objects universe
  - Process
  - Device
  - Memory location
  - Subjects

# Access Control Model

		OBJECTS								
		subjects			files		processes		disk drives	
		S <sub>1</sub>	S <sub>2</sub>	S <sub>3</sub>	F <sub>1</sub>	F <sub>1</sub>	P <sub>1</sub>	P <sub>2</sub>	D <sub>1</sub>	D <sub>2</sub>
SUBJECTS	S <sub>1</sub>	control	owner	owner control	read *	read owner	wakeup	wakeup	seek	owner
	S <sub>2</sub>		control		write *	execute			owner	seek *
	S <sub>3</sub>			control		write	stop			

\* - copy flag set

# Access Control Function

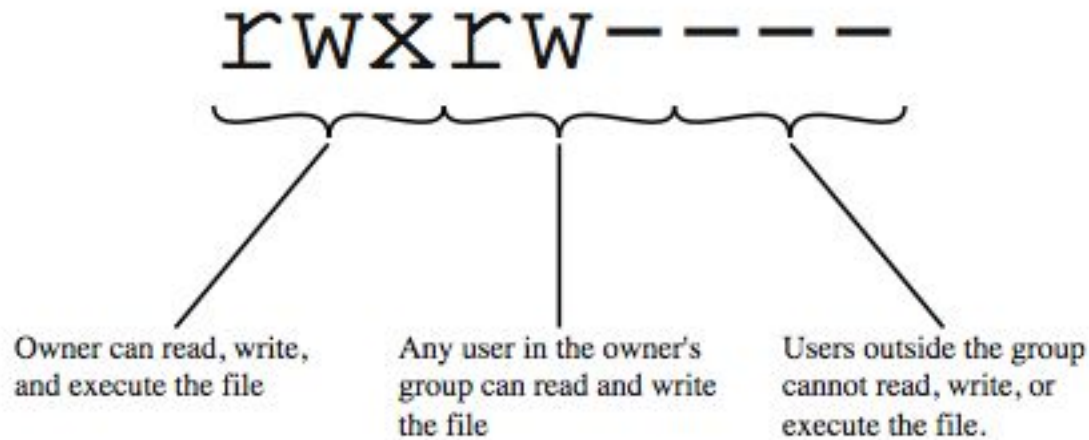

# Protection Domains

- set of objects with associated access rights
- in access matrix view, each row defines a protection domain
  - but not necessarily just a user
  - may be a limited subset of user's rights
  - applied to a more restricted process
- may be static or dynamic

# UNIX File Concepts

- UNIX files administered using inodes
  - It is a control structure with key info on file
    - attributes, permissions of a single file
    - One active inode per each file
  - have inode table / list for all files on a disk
    - copied to memory when disk mounted
- directories form a hierarchical tree
  - may contain files or other directories
  - Each of these with its own inode

# UNIX File Access Control

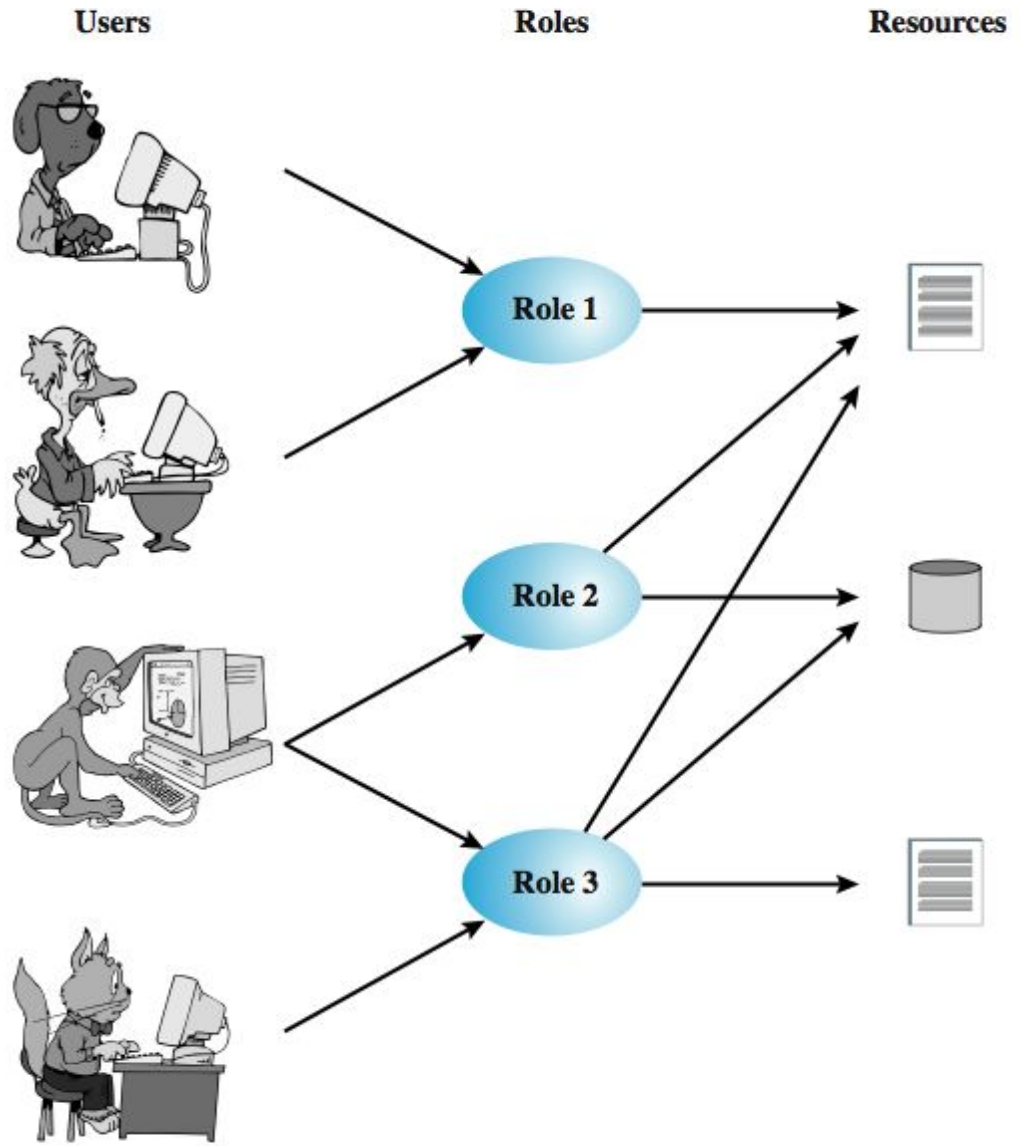

# UNIX File Access Control

- “set user ID”(SetUID) or “set group ID”(SetGID)
  - system temporarily uses rights of the file owner / group in addition to the real user’s rights when making access control decisions
  - enables privileged programs to access files / resources not generally accessible
- sticky bit
  - on directory limits rename/move/delete to owner
- superuser
  - is exempt from usual access control restrictions

# Role-Based Access Control

# Role-Based Access Control

	$R_1$	$R_2$	...	$R_n$
$U_1$	×			
$U_2$	×			
$U_3$		×		×
$U_4$				×
$U_5$				×
$U_6$				×
...				
$U_m$	×			

		OBJECTS								
		R <sub>1</sub>	R <sub>2</sub>	R <sub>n</sub>	F <sub>1</sub>	F <sub>1</sub>	P <sub>1</sub>	P <sub>2</sub>	D <sub>1</sub>	D <sub>2</sub>
ROLES	R <sub>1</sub>	control	owner	owner control	read *	read owner	wakeup	wakeup	seek	owner
	R <sub>2</sub>		control		write *	execute			owner	seek *
	•									
	•									
	R <sub>n</sub>			control		write	stop			

# Summary

- introduced access control principles
  - subjects, objects, access rights
- discretionary access controls
  - access matrix, access control lists (ACLs), capability tickets
  - UNIX traditional and ACL mechanisms
- role-based access control
